

# National University of Computer and Emerging Sciences, Lahore Campus

	Course Name:	Computer Architecture	Course Code:	EE204
	Program:	BS (Computer Science)	Semester:	Fall2018
	Duration:	3 hours	Total Marks:	70
	Paper Date:	31-12-2018	Weight	45
	Exam Type:	Final	Page(s):	7

**Student : Name:** \_\_\_\_\_ **Roll No.** \_\_\_\_\_ **Section:** \_\_\_\_\_

**Instruction:** 1. Attempt all questions in the provided space. You can use rough sheets but it should not be attached.

2. If you think some information is missing, write assumption and solve accordingly.

## Question 1 [10 marks] (Multiple correct options can be selected in each question)

- A decoder having 64 outputs will have \_\_\_\_\_ inputs.  
 A. 4  
**B. 6**  
 C. 8  
 D. 64
- A single cycle machine has separate instruction and data memory in order to avoid \_\_\_\_\_.  
 A. Branch Hazard  
 B. Data Hazard  
**C. Structural Hazard**  
 D. Memory Hazard
- The total number of bits needed for a cache is a function of  
 A. Data bits, Tag bits and index bits  
 B. Data bits, Block size, and valid bit  
 C. Tag bits, index bits and Data Block size  
**D. Data bits, Tag bits, and valid bit**
- What are the side effects of increasing the block size to a much larger value  
 A. Use of spatial locality principle decreases  
**B. The number of blocks in cache decreases**  
**C. Cost of cache miss increases**  
 D. All of the above
- In a write-back policy, the updated data is written to  
**A. Cache only**  
 B. Cache and main memory simultaneously  
 C. Memory only  
 D. Cache and Buffer
- Suppose 10% of the instructions are stores and write through policy is used to handle writes. If the CPI without cache misses was 1.0, What will be the CPI if we spend 100 extra cycles on every write to the memory?  
 Answer: **CPI of  $1.0 + 100 \times 10\% = 11$**
- The type of hazard that occurs when executing instructions cannot access hardware simultaneously are called **structural hazards**
- Cause register in case of exception records **cause of the exception**
- If we have compiler that can produce code by rearranging instructions and inserting NOPs, we don't need underlying hazard detection and forwarding hardware. **True/False?**
- In virtual memory, size of the physical address is always greater than the virtual address because more space can be accessed through main memory and the disk collectively. **True/False?**

## Question 2

### Part a: [1 + 1 + 1 + 1 marks]

Consider the following code snippet's execution on a 5-stage pipelined processor with hazard detection and forwarding fully implemented.

Instruction 1: Or R1,R1,R3  
Instruction 2: Lw R2, 20(R2)  
Instruction 3: Lw R3, 0(R1)  
Instruction 4: sw R2,40(R1)  
Instruction 5: Add R4,R5,t4  
Instruction 6: Add R4,R5,R5  
Instruction 7: Add R4,R6,R6

Suppose the execution of the code starts in the first clock cycle.

1. Is the following condition true in 5th clock cycle?

MEM/WB.RegisterRd = ID/EX.RegisterRs **True/False**

Reason: R1=R1

2. Is the following condition true in 5th clock cycle?

MEM/WB.RegisterRd = ID/EX.RegisterRt **True/False**

Reason: R1 !=R3

Is the following condition true in 6th clock cycle?

MEM/WB.RegisterRd = ID/EX.RegisterRs **True/False**

Reason: R2 != R1

Is the following condition true in 6th clock cycle?

MEM/WB.RegisterRd = ID/EX.RegisterRt **True/False**

Reason: R2 = R2

### Part b: [2+2 marks]

Consider the following facts for the page table and answer the questions below.

- a) Each page table entry consists of a physical page number, 1 valid bit, 1 dirty bit
- b) Virtual addresses are 32 bits - Physical addresses are 26 bits - The page size is 8 Kbytes

1. How many pages a process can have? **2<sup>19</sup> pages**

2. What is the size of the page table?  $2^{19} * 15 \text{ bits}$

**Part c: [5 marks]**

Considering two code sequences that require the following instruction counts

	Code Sequence 1	Code Sequence 2
<b>Load Instructions Count</b>	5	4
<b>Branch Instructions Count</b>	2	2
<b>ALU Instructions Count</b>	10	15

Following details are provided for the processor

1. Full forwarding and hazard detection unit is implemented
2. Branch decision hardware is implemented in the decode stage and the forwarding unit has been modified for forwarding data from earlier instructions to the decode stage
3. Branch prediction hardware always predicts the branch as taken. Penalty for misprediction is 1 clock cycle. Branch prediction accuracy is 80%
4. All load instructions are immediately followed by the ALU instructions that use the loaded data  
Example: `lw R1, 0(R2)`  
          `add R2, R1, R3`

Compute average CPI (including stalls) for Code sequence 1 and 2. Show all steps of the calculations.

CPI for load instructions = 2

CPI for branch instructions =  $2 * 20\% + 1 * 80\% = 1.2$

CPI for ALU instructions = 1

For code Sequence 1:  $CPI = 2*5 + 1.2*2 + 1*10 = 22.4/17 = 1.32$

For code Sequence 2:  $CPI = 2*4 + 1.2*2 + 1*15 = 25.4/21 = 1.20$

### Question 3 [8+11+8]

Code	Instructions
FOR: ld R1,100(R6) ld R2,200(R6) add R5,R2,R1 ld R4,0(R5) addi R6,R6,4 and R4,R5,R4 st R4,0(R5) beq R6,R7, FOR	<ul style="list-style-type: none"> <li>○ We have 5-stage MIPS pipelined processor where Memory and Branch instructions use all 5 stages however ALU instructions use 4 stages: no cycle in memory and 1 cycle in all other 4 stages. Branch instructions consumes 1 cycle in each stage. Memory type instructions take 2 cycles in memory and 1 cycle in all other stages.</li> <li>○ Instructions can be completed out of order. Instructions are fetched and decoded in order however execution, memory and writeback can be out of order.</li> <li>○ An instruction will only enter the execution stage if it does not cause a ReadAfterWrite, WriteAfterRead or WriteAfterWrite hazard.</li> <li>○ There is only one unit in each stage so only one instruction can enter a stage at a time, and in case multiple instructions are ready, the oldest one will go first.</li> <li>○ Full Forwarding is implemented</li> <li>○ There is no register renaming</li> </ul>

- a. Fill in the following table pointing for each instruction, the pipeline stages activated in each clock cycle. For example instruction 1 is fetched in 1<sup>st</sup> cycle, decoded in 2<sup>nd</sup> as shown below

Cycle Inst	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30

(3)																														
(4)																														
(5)																														
(6)																														
(7)																														
(8)																														

- b. Unroll the loop for level 2 (two iterations only), add stalls and then reschedule to remove as many stalls as possible. For this part ignore structural hazards. You have to consider only data and control hazards.

Code after loop unrolling	Code with added stalls	Optimized schedule of instruction

- c. Consider the given program (used in part a) to be executed on 2-issue superscalar processor with following specification.
- o There are two generic arithmetic execution units
  - o Memory type instructions take 2 cycles in memory and arithmetic instruction does not use memory stage.
  - o Full Forwarding is implemented
  - o In case of false dependencies, write back should be in order. No need to wait in decode stage

[illegible]

- a. Fill in the following table pointing for each instruction, the pipeline cycle. For example instruction 1 is fetched in 1<sup>st</sup> cycle, decoded

Cycle Inst	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
(1)	F	D	e	m	M	W												
(2)		F	D	e	-	m	m	W										
(3)			F	D	-	-	-	e	W									
(4)				F	D	-	-	-	e	m	m	W						
(5)					F	D	e	-	-	W								
(6)						F	D	-	-	-	-	e	W					
(7)							F	D	e	-	-	-	m	m	W			
(8)								F	D	e	m	-	-	W				

Unroll the loop for level 2 (two iterations only), add stalls and then reschedule to remove as many stalls as possible. For this part ignore structural hazards. You have to consider only data and control hazards.

Q4: Consider a memory sub-system—with 16-bit word-size and addresses—that has two levels of cache (L1 and L2). L1 is a direct-mapped cache with 16 bytes block size and cache capacity of 4 KB. L2 is an 8-way set associative cache with 256 bytes block size and cache capacity of 32 KB. (20 marks)

a. Calculate the size of tag, index, and offset fields for the L1 cache (3 marks)	Number of tag bits	4 bits								
	Number of index bits	8 bits								
	Number of offset (word + byte) bits	4 bits (3 + 1)								
b. Calculate the size of tag, index, and offset fields for the L2 cache (3 marks)	Number of tag bits	4 bits								
	Number of index bits	4 bits								
	Number of offset (word + byte) bits	8 bits (7 + 1)								
c. A test application attempts to read the following memory address (16-bit addresses). List all generated events that might take place for each read access. Possible events include L1-Hit, L1-Miss, L2-Hit, L2-Miss, and Mem (for memory read). Both (10 marks)  Note that memory blocks are only transferred between adjacent memory levels. For eviction of blocks, Least Recently Used (LRU) approach is used by L1 and L2 caches. The caches are initially empty.  The following cases (see below) generate the following events (see below). Use this information to fill the table in the right-box.  <table><tr><td>Cases</td><td>Generated Events</td></tr><tr><td>L1 Hit</td><td>L1-Hit</td></tr><tr><td>L2-Hit</td><td>L1-Miss, L2-Hit</td></tr><tr><td>Memory Access</td><td>L1-Miss, L2-Miss, Mem</td></tr></table>	Cases	Generated Events	L1 Hit	L1-Hit	L2-Hit	L1-Miss, L2-Hit	Memory Access	L1-Miss, L2-Miss, Mem	Memory Address (to read from)	Generated Events (L1-Hit, L1-Miss, L2-Hit, L2-Miss, and Mem)
	Cases	Generated Events								
	L1 Hit	L1-Hit								
	L2-Hit	L1-Miss, L2-Hit								
	Memory Access	L1-Miss, L2-Miss, Mem								
	0x1562	L1-Miss, L2-Miss, Mem								
	0x1588	L1-Miss, L2-Hit								
	0x1581	L1-Hit								
	0x1562	L1-Miss, L2-Hit								
	0x4562	L1-Miss, L2-Miss, Mem								
	0x45BC	L1-Miss, L2-Hit								
	0x4562	L1-Miss, L2-Hit								
	0x1562	L1-Miss, L2-Hit								
0x45BC	L1-Hit									
0x45B2	L1-Hit									
Assume that the: Clock rate is 2 GHz, L1 access time is 1 cycle, L2 access time is 10 cycles, Memory access time is 100 cycles, L1 hit rate is 60%, L2 hit rate is 70%.  What is the average memory access time? (4 marks)	AMAT = Time for a hit + Miss Rate x Miss Penalty  AMAT <sub>1</sub> = HitTime <sub>1</sub> + MissRate <sub>1</sub> x (MissPenalty <sub>1</sub> ) MissPenalty <sub>1</sub> = HitTime <sub>2</sub> + MissRate <sub>2</sub> x (MissPenalty <sub>2</sub> )  Since the clock rate is 2 Ghz, clock cycle time is 0.5 ns. AMAT <sub>1</sub> = 5 ns + 0.4 (MissPenalty <sub>1</sub> )  MissPenalty <sub>1</sub> = 5 ns + .3(50ns) = 20 ns  AMAT <sub>1</sub> = 5ns +.4 (20ns) = 8.5 ns
